Caveolae And Lipid Rafts Roles  
Membrane (lipid) rafts and caveolae, a  
subset of rafts, are cellular domains  
that concentrate plasma membrane  
proteins and lipids involved in the  
regulation of cell function. In addition  
to providing signaling platforms for G-  
protein-coupled receptors and certain  
tyrosine kinase receptors,  
rafts/caveolae can influence redox  
signaling.

Caveolae are flask-shaped invaginations of the plasma membrane found in numerous cell types and are particularly abundant in endothelial cells and adipocytes. The lipid composition of caveolae largely matches that of lipid rafts microdomains that are particularly enriched in cholesterol, sphingomyelin, glycosphingolipids, and saturated fatty acids.

Caveolae and Lipid Rafts in  
Endothelium: Valuable ...

Some proteins require interaction with caveolin, implying that such proteins will preferentially localize in caveolae (relative to lipid rafts, such as G s and G i, in the study of Oh & Schnitzer,

# Where To Download Caveolae And Lipid Rafts

2001), while other proteins do not interact with caveolin and thus would be found in the lipid environment common to both lipid rafts and caveolae. As will be discussed below, the cell type in which a given signaling protein is expressed may also be a critical determinant of lipid raft or caveolar ...

The evolving role of lipid rafts and caveolae in G protein ...

Cholesterol is a major constituent of lipid rafts and its concentration at the plasma membrane generally regulates raft-dependent phenomena such as signaling and endocytosis. Cholesterol is one of the key factors determining long-range protein mobility at the cell surface ( Kenworthy et al., 2004 ).

The lipid composition of caveolae largely matches that of lipid rafts microdomains that are particularly enriched in cholesterol, sphingomyelin, glycosphingolipids, and saturated fatty acids. Unlike lipid rafts, whose existence remains quite elusive in living cells, caveolae can be clearly distinguished by electron microscope.

In biology, caveolae (Latin for "little caves"; singular, caveola), which are a special type of lipid raft, are small (50–100 nanometer) invaginations of the plasma membrane in many vertebrate cell types, especially in endothelial cells, adipocytes and embryonic notochord cells. They were originally discovered by E. Yamada in 1955. These flask-shaped structures are rich in proteins as well ...

Caveolae - Wikipedia

Caveolins are synthesized as monomers and transported to the Golgi apparatus. During their subsequent transport through the secretory pathway, caveolins associate with lipid rafts and form oligomers (14-16 molecules). These oligomerized caveolins form the caveolae. The presence of caveolin leads to a local change in morphology of the membrane.

The Role of Caveolae and Noncaveolar Rafts in Endocytosis ...  
Flotillin and caveolins can recruit signaling molecules into lipid rafts, thus playing an important role in neurotransmitter signal transduction. It has been proposed that these microdomains spatially organize signaling molecules to promote kinetically favorable interactions which are necessary for signal transduction.

## Lipid raft - Wikipedia

Cholesterol plays a critical role in differentiating and maintaining cell surface microdomains of differing lipid composition, particularly sphingolipid rafts. Cholesterol- and sphingolipid-rich rafts in association with a structural protein, caveolin-1, form caveolae, flask-shaped invaginations in the plasma membrane.
